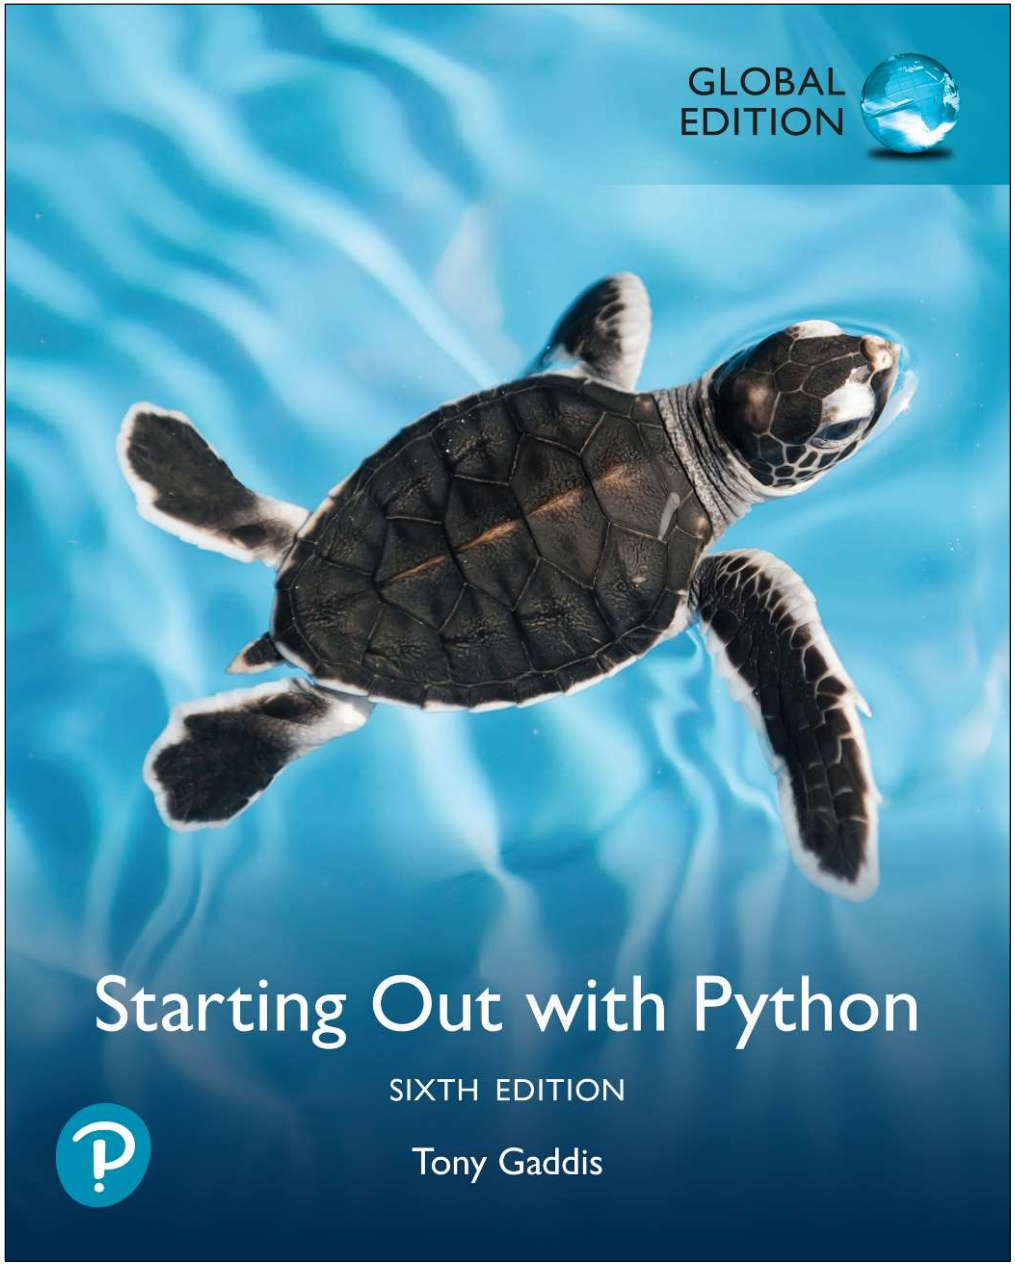
CHAPTER 4

Repetition Structures



Topics

- Introduction to Repetition Structures
- The `while` Loop: a Condition-Controlled Loop
- The `for` Loop: a Count-Controlled Loop
- Calculating a Running Total
- Sentinels
- Input Validation Loops
- Nested Loops
- Using `break`, `continue`, and `else` with Loops
- Turtle Graphics: Using Loops to Draw Designs

Introduction to Repetition Structures

- **Often must write code that performs the same task multiple times**
  - Disadvantages to duplicating code
    - Makes program large
    - Time consuming
    - May need to be corrected in many places
- **Repetition structure: makes computer repeat included code as necessary**

Condition-Controlled and Count-Controlled Loops

- **There are two broad categories of loops:**
  - Condition-controlled
    - uses a true/false condition to control the number of times the loop iterates
  - Count-controlled
    - repeats a specific number of times

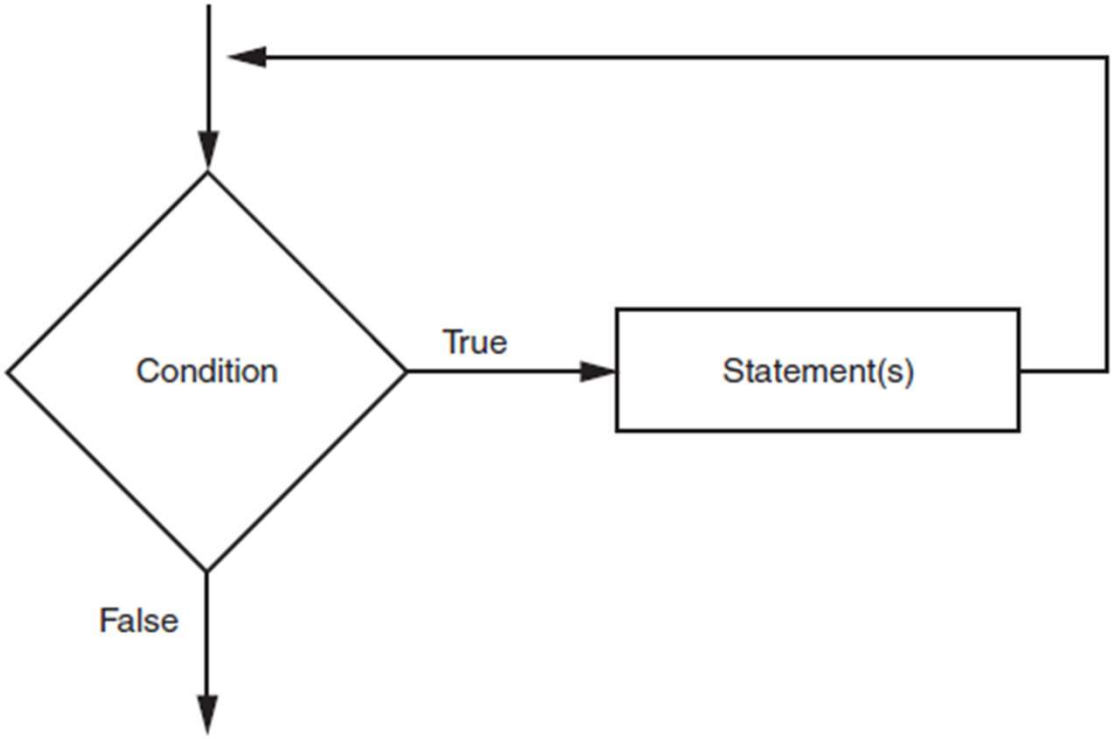
The `while` Loop: a Condition-Controlled Loop

- **`while` loop: while condition is true, do something**
  - Two parts:
    - Condition tested for true or false value
    - Statements repeated as long as condition is true
  - In flow chart, line goes back to previous part
  - General format:

```
while condition:
    statements
```

The `while` Loop: a Condition-Controlled Loop (cont'd.)

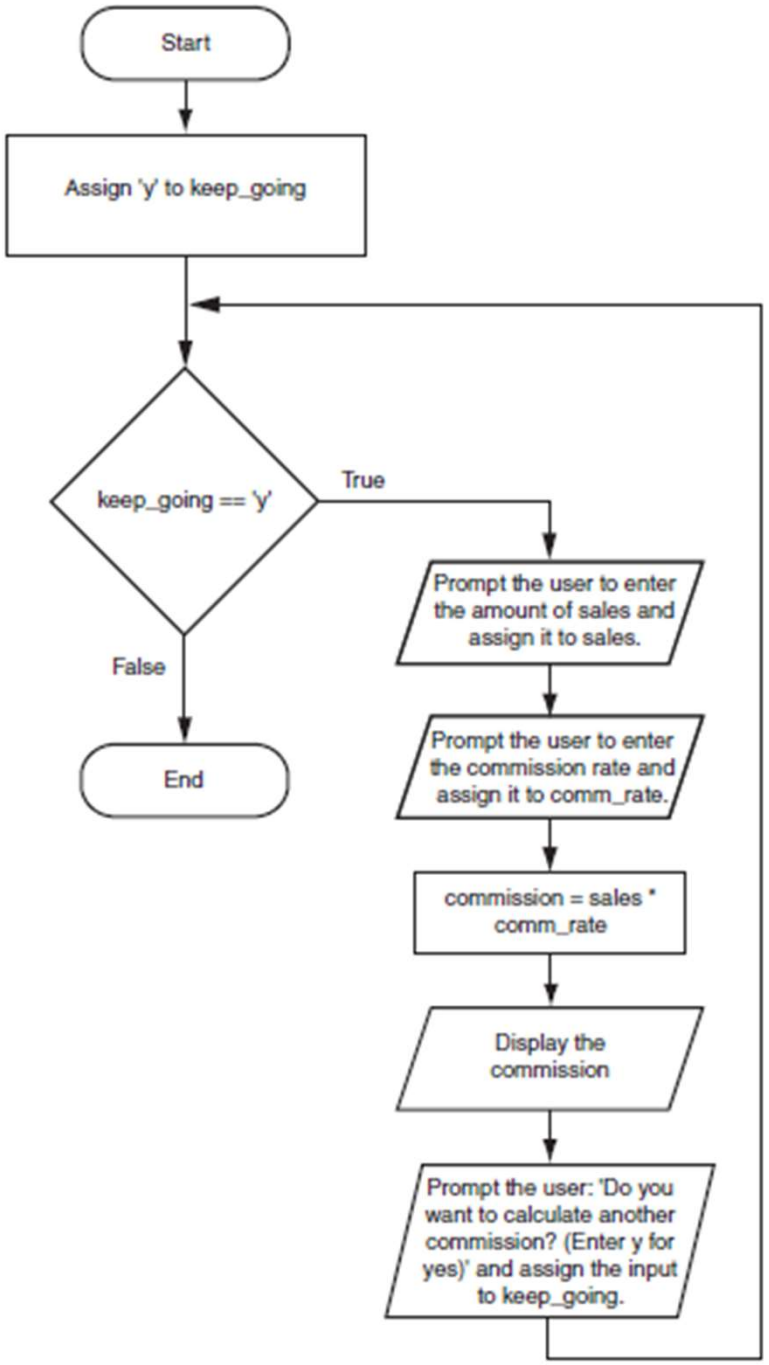
Figure 4-1 The logic of a `while` loop



The `while` Loop: a Condition-Controlled Loop (cont'd.)

- **In order for a loop to stop executing, something has to happen inside the loop to make the condition false**
- **Iteration: one execution of the body of a loop**
- **`while` loop is known as a *pretest* loop**
  - Tests condition before performing an iteration
    - Will never execute if condition is false to start with
    - Requires performing some steps prior to the loop

Figure 4-3 Flowchart for Program 4-1



Infinite Loops

- **Loops must contain within themselves a way to terminate**
  - Something inside a `while` loop must eventually make the condition false
- **Infinite loop: loop that does not have a way of stopping**
  - Repeats until program is interrupted
  - Occurs when programmer forgets to include stopping code in the loop

Using the `while` Loop as a Count-Controlled Loop

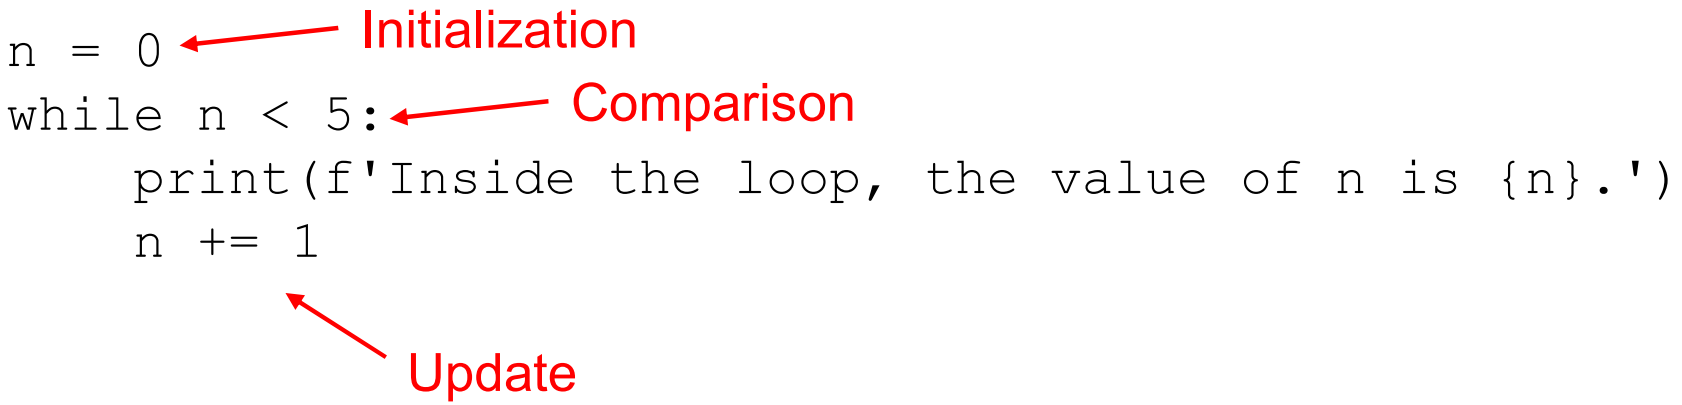
- **The `while` loop is inherently a condition-controlled loop**
  - It repeats as long as a Boolean condition is true
- **However, you can use the `while` loop as a count-controlled loop by pairing it with a counter variable**
- **A counter variable is assigned a unique value during each iteration of a loop.**
- **It is called a *counter* variable because it can be used to count the number of times the loop iterates**

Using the `while` Loop as a Count-Controlled Loop

- **A count-controlled while loop must perform three actions:**
  - **Initialization**: The counter variable must be initialized to a suitable starting value before the loop begins.
  - **Comparison**: The loop must compare the counter variable to a suitable ending value, to determine whether the loop should iterate or not.
  - **Update**: During each iteration, the loop must update the counter variable with a new value.

Using the `while` Loop as a Count-Controlled Loop

- **Example**



- **Initialization**: The variable `n` is initialized with 0
- **Comparison**: The loop iterates as long as `n` is less than 5
- **Update**: 1 is added to `n`

Single-Line `while` Loops

- If there is only one statement in the body of a `while` loop, you can write the entire loop on one line.
- General format:

```
while condition: statement
```

- Example:

```
n = 0
while n < 10: n += 1
```

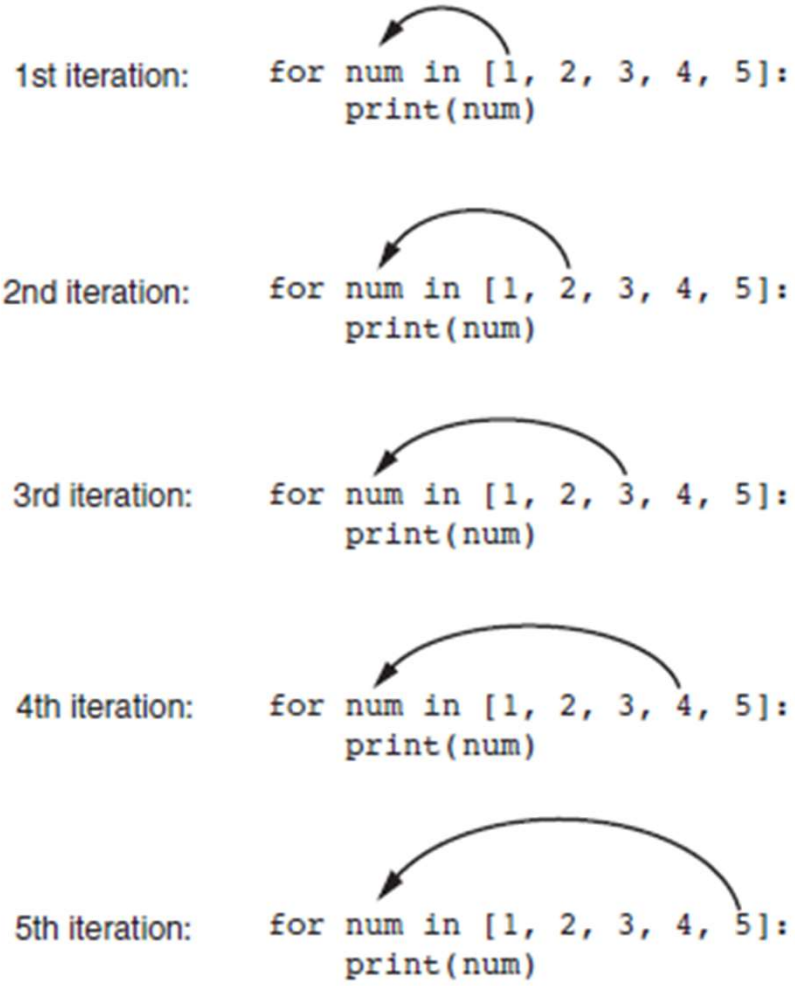
The `for` Loop: a Count-Controlled Loop

- **Count-Controlled loop: iterates a specific number of times**
  - Use a `for` statement to write count-controlled loop
    - Designed to work with sequence of data items
      - Iterates once for each item in the sequence
    - General format:

```
for variable in [val1, val2, etc]:
    statements
```

    - Target variable: the variable which is the target of the assignment at the beginning of each iteration

Figure 4-4 The `for` loop



Using the `range` Function with the `for` Loop

- **The `range` function simplifies the process of writing a `for` loop**
  - `range` returns an iterable object
    - Iterable: contains a sequence of values that can be iterated over
- **`range` characteristics:**
  - One argument: used as ending limit
  - Two arguments: starting value and ending limit
  - Three arguments: third argument is step value

Using the Target Variable Inside the Loop

- **Purpose of target variable is to reference each item in a sequence as the loop iterates**
- **Target variable can be used in calculations or tasks in the body of the loop**
  - Example: calculate square root of each number in a range

Letting the User Control the Loop Iterations

- **Sometimes the programmer does not know exactly how many times the loop will execute**
- **Can receive range inputs from the user, place them in variables, and call the `range` function in the for clause using these variables**
  - Be sure to consider the end cases: `range` does not include the ending limit

Generating an Iterable Sequence that Ranges from Highest to Lowest

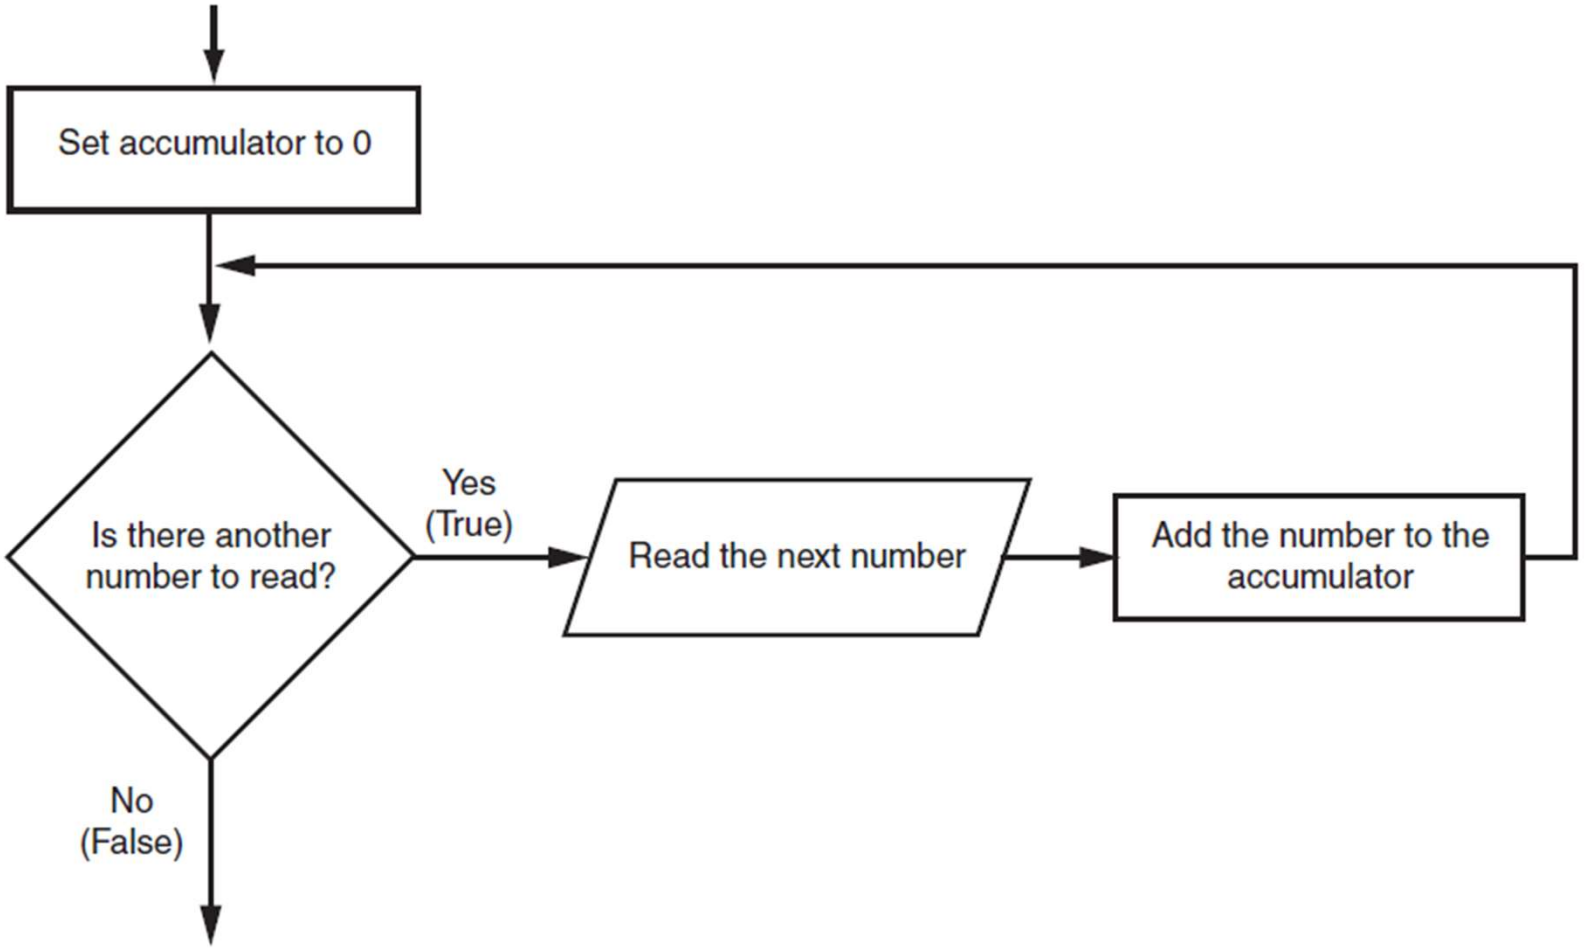
- **The `range` function can be used to generate a sequence with numbers in descending order**
  - Make sure starting number is larger than end limit, and step value is negative
  - Example: `range(10, 0, -1)`

Calculating a Running Total

- **Programs often need to calculate a total of a series of numbers**
  - Typically include two elements:
    - A loop that reads each number in series
    - An *accumulator* variable
  - Known as program that keeps a running total: accumulates total and reads in series
  - At end of loop, accumulator will reference the total

Calculating a Running Total (cont'd.)

Figure 4-6 Logic for calculating a running total



The Augmented Assignment Operators

- **In many assignment statements, the variable on the left side of the = operator also appears on the right side of the = operator**
- **Augmented assignment operators: special set of operators designed for this type of job**
  - Shorthand operators

The Augmented Assignment Operators (cont'd.)

Table 4-2 Augmented assignment operators

Operator	Example Usage	Equivalent To
`+=`	`x += 5`	`x = x + 5`
`-=`	`y -= 2`	`y = y - 2`
`*=`	`z *= 10`	`z = z * 10`
`/=`	`a /= b`	`a = a / b`
`%=`	`c %= 3`	`c = c % 3`

Sentinels

- **Sentinel: special value that marks the end of a sequence of items**
  - When program reaches a sentinel, it knows that the end of the sequence of items was reached, and the loop terminates
  - Must be distinctive enough so as not to be mistaken for a regular value in the sequence
  - Example: when reading an input file, empty line can be used as a sentinel

Input Validation Loops

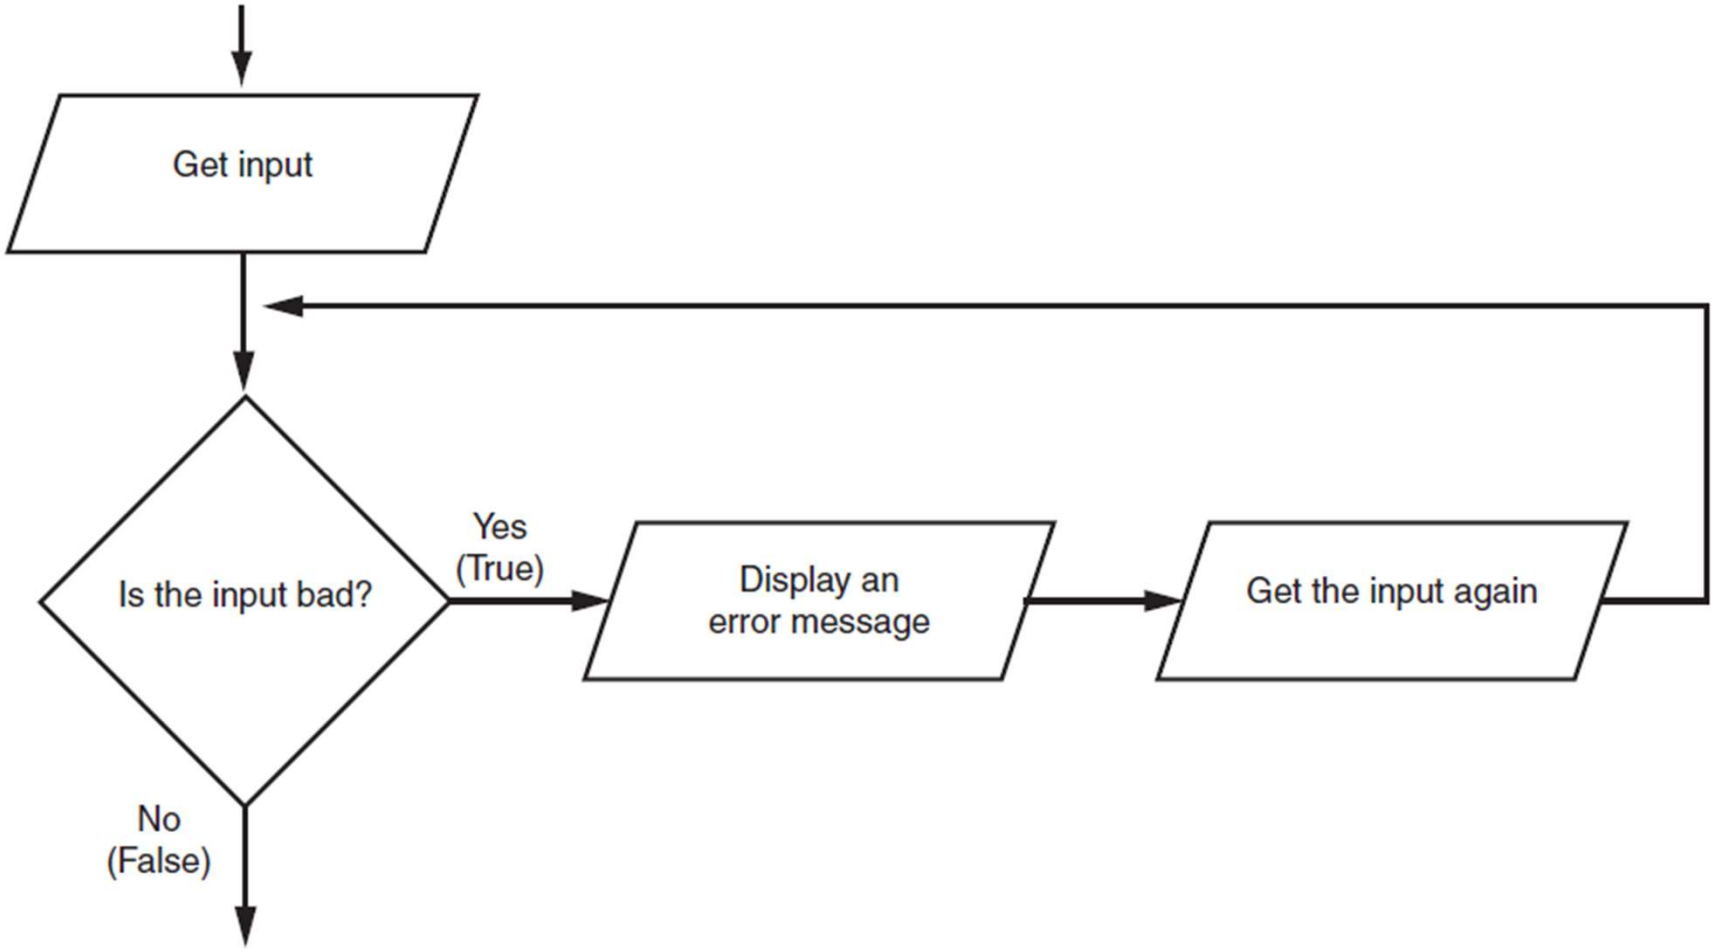
- **Computer cannot tell the difference between good data and bad data**
  - If user provides bad input, program will produce bad output
  - GIGO: garbage in, garbage out
  - It is important to design program such that bad input is never accepted

Input Validation Loops (cont'd.)

- **Input validation: inspecting input before it is processed by the program**
  - If input is invalid, prompt user to enter correct data
  - Commonly accomplished using a `while` loop which repeats as long as the input is bad
    - If input is bad, display error message and receive another set of data
    - If input is good, continue to process the input

Input Validation Loops (cont'd.)

Figure 4-7 Logic containing an input validation loop



Input Validation Loops (cont'd.)

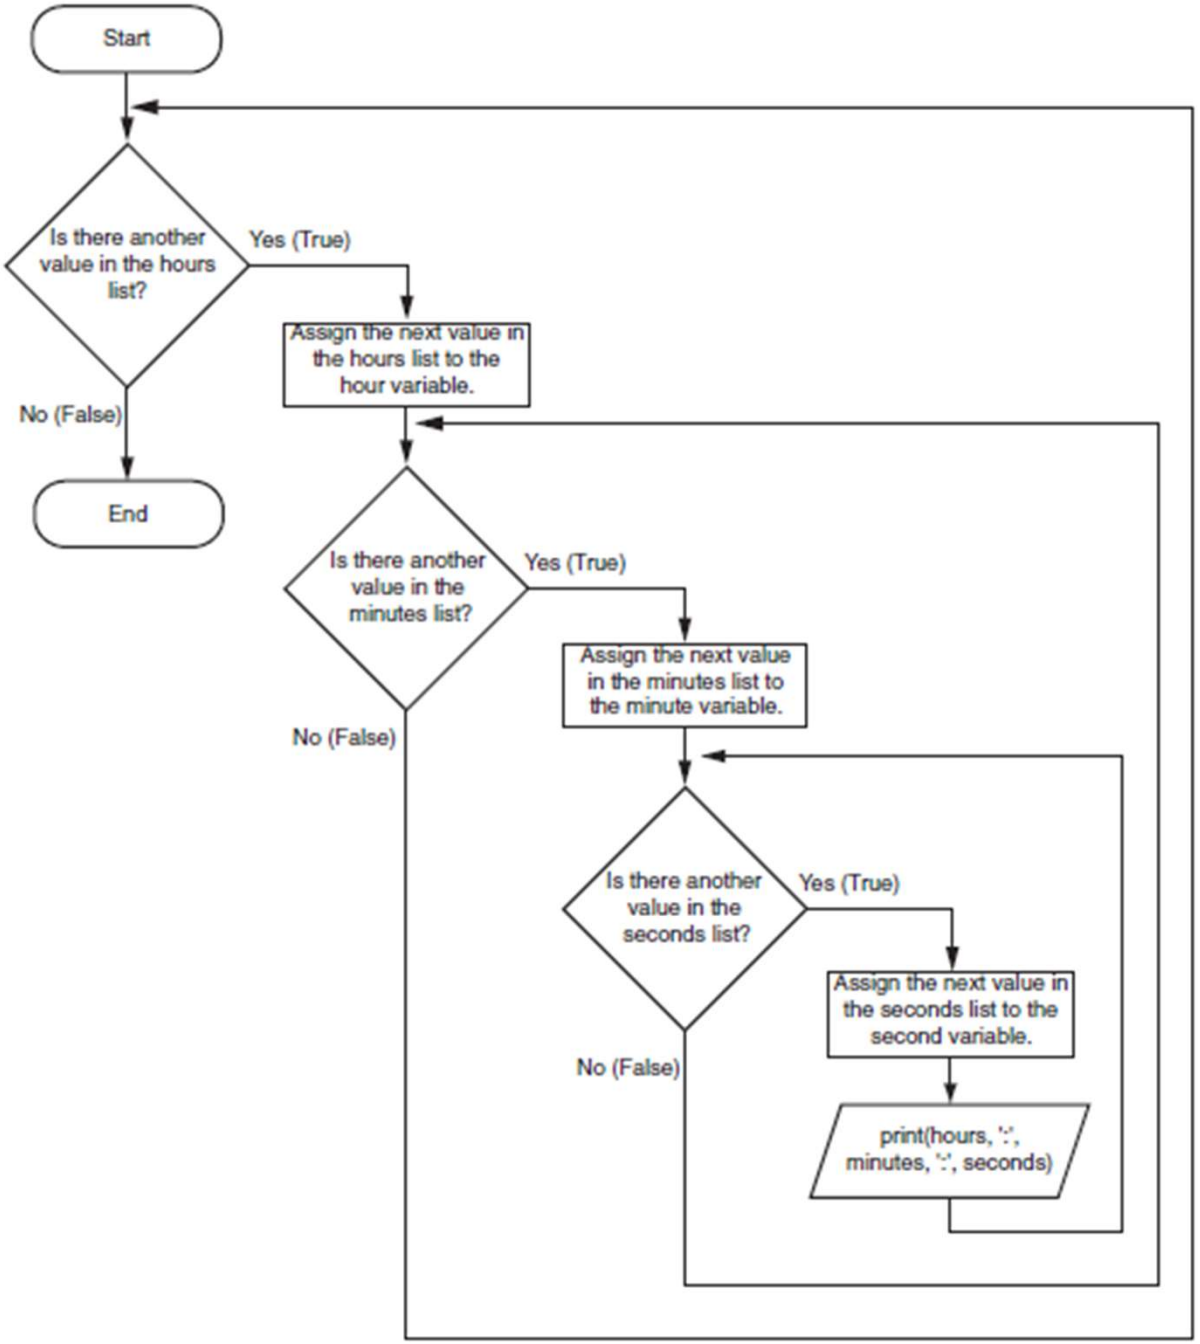
- **Using the walrus operator in an input validation loop**
  - You can use the walrus operator to create an assignment expression that combines the priming read with the input validation loop
  - **Example**:

```
while (score := int(input('Enter your score: '))) < 0:
        print('The score cannot be negative.'
```

Nested Loops

- **Nested loop: loop that is contained inside another loop**
  - Example: analog clock works like a nested loop
    - Hours hand moves once for every twelve movements of the minutes hand: for each iteration of the “hours,” do twelve iterations of “minutes”
    - Seconds hand moves 60 times for each movement of the minutes hand: for each iteration of “minutes,” do 60 iterations of “seconds”

Figure 4-8 Flowchart for a clock simulator



Nested Loops (cont'd.)

- **Key points about nested loops:**
  - Inner loop goes through all of its iterations for each iteration of outer loop
  - Inner loops complete their iterations faster than outer loops
  - Total number of iterations in nested loop:

number of iterations of inner loop X *number of iterations of outer loop*

The `break` Statement

- **The `break` statement causes a loop to terminate**

```
n = 0
while n < 100:
    print(n)
    if n == 5:
        break
    n += 1

print(f'The loop stopped and n is {n}.')
```

This statement causes the loop to stop

Program Output

```
0
1
2
3
4
5
The loop stopped and n is 5.
```

The `continue` Statement

- The `continue` statement causes the current iteration of a loop to end early

- When the `continue` statement is executed, all the statements in the body of the loop that appear after it are ignored, and the loop begins its next iteration (if there is a next iteration)

The `continue` Statement

- **Example:**

```
n = 0
while n < 10:
    n += 1
    if n % 3 == 0:
        continue
    print(n)
```

This statement ends the current iteration and causes the loop to skip to the next iteration.

Program Output

```
1
2
4
5
7
8
10
```

The `else` Clause with a Loop

- **Loops in Python can have an optional `else` clause.**

```
while condition:
    statement
    statement
    etc.
else:
    statement
    statement
    etc.
```

```
for variable in [value1, value2, etc.]:
    statement
    statement
    etc.
else:
    statement
    statement
    etc.
```

The `else` Clause with a Loop

- An `else` clause in a loop is useful only when the loop contains a `break` statement.
- The block of statements that appears after the `else` clause executes only when the loop terminates normally, without encountering a `break` statement.
- If the loop terminates because of a `break` statement, the `else` clause will not execute its block of statements.

The `else` Clause with a Loop

- **Example:**

```
for n in range(10):
    if n == 5:
        print('Breaking out of the loop.')
        break
    print(n)
else:
    print(f'After the loop, n is {n}.')
```

Program Output

```
0
1
2
3
4
Breaking out of the loop.
```

The `else` clause did not execute because the `break` statement executed

The `else` Clause with a Loop

- **Example:**

```
for n in range(3):
    if n == 5:
        print('Breaking out of the loop.')
        break
    print(n)
else:
    print(f'After the loop, n is {n}.')
```

Program Output

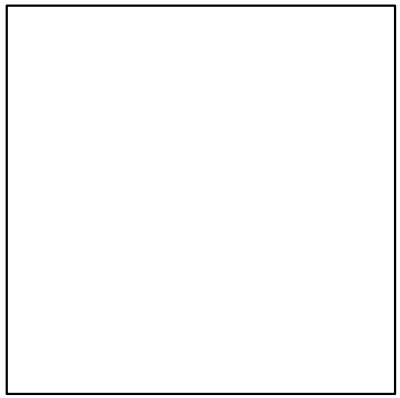
```
0
1
2
After the loop, n is 2.
```

The `break` statement did not execute, so the `else` clause executed.

Turtle Graphics: Using Loops to Draw Designs

- **You can use loops with the turtle to draw both simple shapes and elaborate designs. For example, the following for loop iterates four times to draw a square that is 100 pixels wide:**

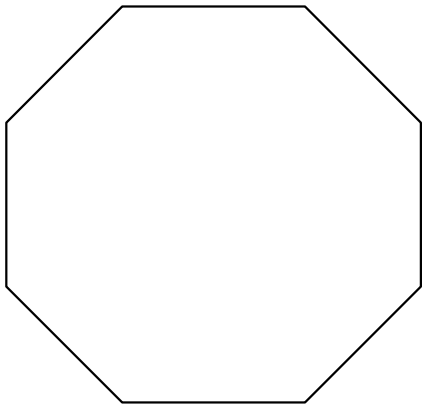
```
for x in range(4):
    turtle.forward(100)
    turtle.right(90)
```



Turtle Graphics: Using Loops to Draw Designs

- **This `for` loop iterates eight times to draw the octagon:**

```
for x in range(8):
    turtle.forward(100)
    turtle.right(45)
```

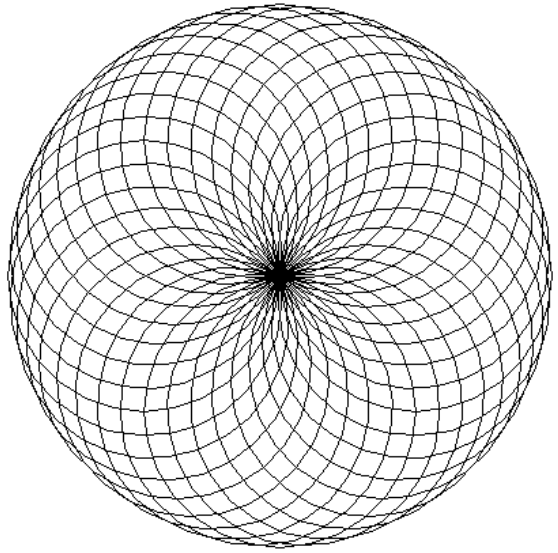


Turtle Graphics: Using Loops to Draw Designs

- **You can create interesting designs by repeatedly drawing a simple shape, with the turtle tilted at a slightly different angle each time it draws the shape.**

```
NUM_CIRCLES = 36     # Number of circles to draw
RADIUS = 100         # Radius of each circle
ANGLE = 10           # Angle to turn

for x in range(NUM_CIRCLES):
    turtle.circle(RADIUS)
    turtle.left(ANGLE)
```



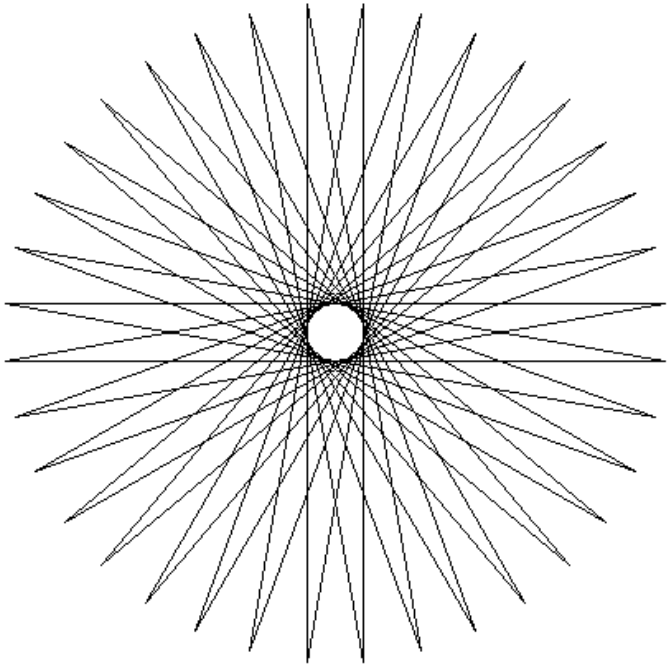
Turtle Graphics: Using Loops to Draw Designs

- **This code draws a sequence of 36 straight lines to make a "starburst" design.**

```
START_X = -200       # Starting X coordinate
START_Y = 0          # Starting Y coordinate
NUM_LINES = 36       # Number of lines to draw
LINE_LENGTH = 400    # Length of each line
ANGLE = 170          # Angle to turn

turtle.hideturtle()
turtle.penup()
turtle.goto(START_X, START_Y)
turtle.pendown()

for x in range(NUM_LINES):
    turtle.forward(LINE_LENGTH)
    turtle.left(ANGLE)
```



Summary

- **This chapter covered:**
  - Repetition structures, including:
    - Condition-controlled loops
    - Count-controlled loops
    - Nested loops
  - Infinite loops and how they can be avoided
  - `range` function as used in `for` loops
  - Calculating a running total and augmented assignment operators
  - Use of sentinels to terminate loops
  - Using loops to draw turtle graphic designs
